# Part 2: Radioactive Material Monitoring in the Water Environment in and around Fukushima Prefecture (FY2017)

# 1 Objective and Details

# 1.1 Objective

This monitoring was conducted in response to the Fukushima NPS Accident for the purpose of clarifying the distribution of the accident-derived radioactive materials in the water environment.

## 1.2 Details

#### (1) Locations

The survey was conducted mainly in and around Fukushima prefecture at around 600 locations for public water areas and at around 400 locations for groundwater. Specific locations are shown in Figure 1.2-1.

## (2) Targets

For public water areas (rivers, lakes, and coastal areas), water and sediment were surveyed. Additionally, radioactivity in soil in the surrounding environment (riverbeds, etc.) near the sampling locations was also surveyed as reference.

Radioactivity in groundwater was also measured.

#### (3) Frequencies and periods

The monitoring for public water areas was conducted two to 10 times a year (varying by location). The monitoring for groundwater was conducted one to four times a year (varying by location).

## (4) Conducted analyses

Primarily, analyses of Cs-134 and Cs-137 were conducted for the subject samples.

Additionally, analyses on Sr-89, Sr-90 and other artificial radionuclides were also conducted for some of the samples.

## (5) Compilation and evaluation of results

The results of the measurement are compiled and released sequentially as preliminary reports on the Ministry of the Environment website.

This report is the compilation of the overall monitoring results, and the details of individual monitoring surveys are available on the following website.

http://www.env.go.jp/en/water/rmms/surveys.html

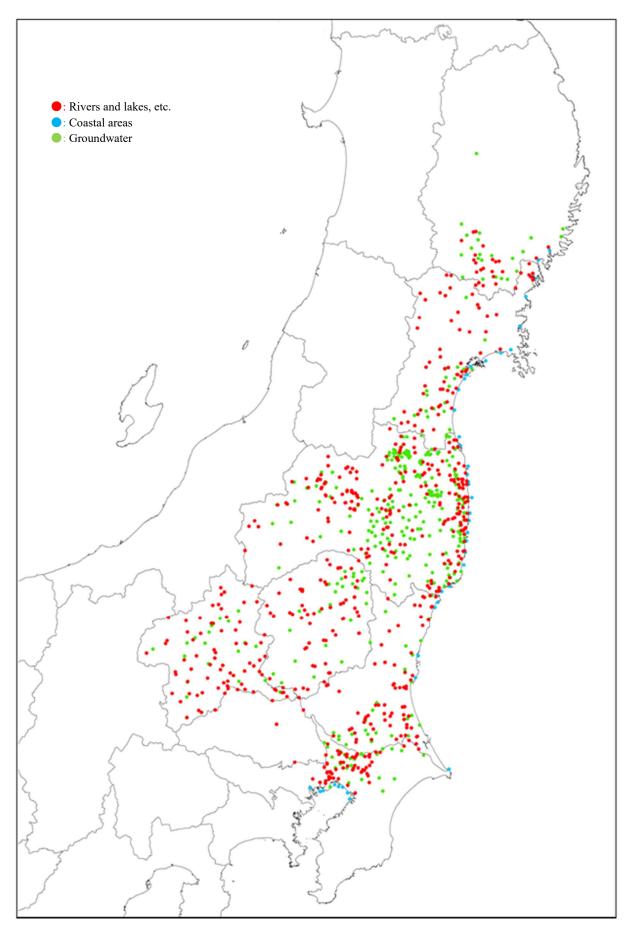

Figure 1.2-1 Map showing locations for the Post-Earthquake Monitoring in FY2017

# 2 Survey Methods and Analysis Methods

# 2.1 Survey methods

Samples were collected at predetermined locations (for public water areas and groundwater) and the following analyses of radioactive materials were conducted.

Samples were collected based on the following guidelines in principle, as outlined below.

- Water Quality Survey Method (Sep 30, 1971; Notice Kansuikan No. 30 issued by the Director General of the Water Quality Preservation Bureau, Ministry of the Environment)
- Sediment Survey Method (Aug 8, 2012; Notice Kansuitaisuihatsu No. 120725002 issued by the Director General of the Environmental Management Bureau, Ministry of the Environment)
- Groundwater Quality Survey Method (Sep 14, 1989; Notice Kansuikan No. 189 issued by the Director General of the Water Quality Preservation Bureau, Ministry of the Environment)
- Environmental Sample Collection Method (1983, MEXT's Radioactivity Measurement Method Series)
- Sample Pretreatment for Instrumental Analysis Using Germanium Semiconductor Detectors (1982, MEXT's Radioactivity Measurement Method Series)

# 2.2 Analysis methods

 $\gamma$ -ray spectrometry measurements using a germanium semiconductor detector were conducted for water samples and sediment samples collected from public water areas and for groundwater samples, primarily targeting Cs-134 and Cs-137.

Additionally, analyses on Sr-89, Sr-90 and other artificial radionuclides were also conducted for some of the collected samples. Detected values were indicated with two significant digits in the unit of "Bq/L" in the case of water samples from public water areas and groundwater samples, and in the unit of "Bq/kg" in the case of sediment samples from public water areas. The measurement results were corrected for attenuation, and results were reported as activity concentrations at the time sampling was completed.

Adopted analysis methods were basically in line with the MEXT's Radioactivity Measurement Method Series. Detection limits are as shown in the table below.

Radionucl	ide	Public water areas (water)	Public water areas (sediment)	Groundwater
Radioactive c (Cs-134 and C		Approx. 1 Bq/L	Approx. 10 Bq/kg	Approx. 1 Bq/L
Radioactive	Sr-90	Approx. 1 Bq/L	Approx. 1 Bq/kg (0.16 to 2.9 Bq/kg)	Approx. 1 Bq/L
strontium	Sr-89	-	-	Approx. 1 Bq/L
Other artifi radionuclide		-	-	-

Table 2.2-1 Target values of detection limits for radionuclides in Post-Earthquake Monitoring

\*1: Varies by type of radionuclides.

# 3 Outlines of the Results

The results of the Post-Earthquake Monitoring conducted in FY2017 are as outlined below.

## 3.1 Detection of radioactive cesium

Radioactive cesium (the total of Cs-134 and Cs-137) was detected as follows.

#### (1) Public water areas (water)

In FY2017, radioactive cesium activity concentrations were not all detectable in river water samples and coastal area water samples; from not detectable to 17Bq/L in lake water samples and had a detection rate of 1.7%.

Since FY2011, all prefectures have shown decreasing trends in the detection rate for river water samples (13,000 or more total samples) and lake water samples (8,100 or more total samples). In prefectures other than Fukushima Prefecture, radioactive cesium has not been detected since FY2013 (see Figure 4.1.1-1 and Figure 4.1.1-2). In addition, no survey has detected radioactive cesium in coastal area water samples (3,300 or more total samples) since FY2011.

## (2) Groundwater

Radioactive cesium was not detected in any of the groundwater samples in FY2017.

Looking at the trend from FY2011 onward, radioactive cesium was detected in two samples from Fukushima Prefecture in FY2011 (detected values were 2 Bq/L and 1 Bq/L), and has not been detected in groundwater samples (6,500 or more total samples) since FY2012.

## (3) Public water areas (sediment)

#### 1) Overall trends

In FY2017, radioactive cesium activity concentrations ranged from not detectable to 6,720 Bq/kg and were detected with a detection rate of 85.0% in river sediment samples, from not detectable to 361,000 Bq/kg and with a detection rate of 99.3% in lake sediment samples, and from not detectable to 556 Bq/kg and at a detection rate of 79.0% in coastal area sediment samples.

Additionally, radioactive cesium activity concentrations were less than 200 Bq/kg in almost all areas in rivers and coastal areas (river: approx. 73%, coastal area: approx. 79%), and were less than 3,000 Bq/kg in almost all areas in lakes (approx. 77%) throughout the year.

# 2) Status by location

Because radioactive cesium was detected at many locations, its statuses in respective locations were compared. The status in respective locations were compared and relative concentration levels for detected values and their changes were statistically compiled as shown in "4.1-2 (3) Detection of radioactive materials by location."

Detected concentration levels were compiled as shown in Table 3.1-1.

Locations of Categories A and B (top 10 percentile of the whole) were observed in Hamadori District, Fukushima Prefecture as well as in Nakadori, Fukushima Prefecture and in Ibaraki, Gunma, Chiba (all these were for rivers), and Miyagi Prefectures (for coastal areas).

# Table 3.1-1 Categorization of detected concentration levels for sediment samples from public waterareas (FY2017) (rivers, lakes, and coastal areas)

# <Coastal areas>

		Range				Number	of locations			
Category	Percentile (see Figure 4.1.2-7)	[coastal area sediments]	Iwate	Miyagi	Fukushima	Ibaraki	Chiba	Tokyo	Total	
	(	[Bq/kg (dry)]	Twate	wiiyugi	i ukusiiiina	Touruki	Chibu	TORYO	Number of location	Percentage
А	Upper 5 percentile	375 or more	0	1	1	0	0	0	2	4.8
в	Upper 5 to 10 percentile	261 ~ 375	0	1	1	0	0	0	2	4.8
С	Upper 10 to 25 percentile	132 ~ 261	0	2	2	0	0	2	6	14.3
D	Upper 25 to 50 percentile	30 ~ 132	0	3	7	0	0	1	11	26.2
Е	Lower 50 percentile	30 or less	2	5	4	5	5	0	21	50.0
	Total			12	15	5	5	3	42	100.0

Changes in detected concentration levels were compiled as shown in Figure 3.1-1, which shows Table 4.1.2-48 (described later) graphically.

At most monitoring locations for rivers, a decreasing trend was observed. For lakes, a decreasing or unchanged trend was generally observed with some locations showing fluctuations. For coastal areas, a decreasing trend was generally observed with some locations showing fluctuations.

## 3.2 Detection of radionuclides other than radioactive cesium

#### (1) Sr-89 and Sr-90

Sr-90 was surveyed from FY2011 to FY2017 for sediment samples (approximately 770 samples in total) from public water areas (rivers, lakes, and coastal areas) and for groundwater samples (approximately 340 samples in total) (see Figure 4.2-1). Additionally, from FY2016 to FY2017, water samples (45 samples in FY2016 and three samples in FY2017) were also surveyed at those locations where relatively high concentrations were detected in sediment (1.0 Bq/kg or more in FY2016 and 10 Bq/kg or more in FY2017).

The results of the FY2017 survey were as follows: for public water area sediment samples, Sr-90 concentrations ranged from not detectable to 0.76 Bq/kg and had a detection rate of 33.3% in river sediment; from not detectable to 22 Bq/kg with a detection rate of 94.3% in lakes, and not detectable in coastal areas. As for water samples, Sr-90 was not detected in any public water areas or ground water locations (detection limit: 1 Bq/L for water and 1Bq/kg for sediment).

Sr-89 was not detectable in any of the monitoring surveys conducted for sediment samples from public water areas (a total of 22 samples collected from rivers and lakes in FY2011) or for groundwater samples (a total of approx. 340 samples surveyed from FY2011 to FY2017) (detection limit: 1 Bq/L for water and approximate 2 Bq/kg for sediment).

#### (2) Other artificial radionuclides

None have been detected since FY 2013.

# 4 Results

## 4.1 Radioactive cesium

# 4.1 -1 Water

(1) Public water areas

#### 1) Rivers

Detection of radioactive cesium in river water samples is as shown in Table 4.1.1-1 and Figure 4.1.1-1.

According to the results, all prefectures have shown decreasing trends in the detection rate since FY2011. In FY2017, radioactive cesium was not detected in any locations.

Detected values (the total of Cs-134 and Cs-137) have also shown decreasing trends since FY2011 (detection limit: 1 Bq/L for both Cs-134 and Cs-137 and the same applies to lakes, coastal areas and ground water).

## 2) Lakes

Detection of radioactive cesium in lake water samples is as shown in Table 4.1.1-2 and Figure 4.1.1-2.

According to the results all prefectures have shown decreasing trends in the detection rate since FY2012. Radioactive cesium has not been detected in any locations other than Hamadori District, Fukushima Prefecture since FY2013.

Detected values (the total of Cs-134 and Cs-137) have also shown decreasing trends since FY2012. The measured values in FY2017 ranged from not detectable to 17 Bq/L.

## 3) Coastal areas

Detection of radioactive cesium in coastal area water samples is as shown in Table 4.1.1-3. According to the results, including the past years, radioactive cesium has not been detected in any locations.

#### (2) Groundwater

Detection of radioactive cesium in groundwater samples is as shown in Table 4.1.1-4.

According to the results, radioactive cesium has not been detected in any locations since FY2012 including FY2017.

(\*) Detected in FY2011. Both Cs-134 and Cs-137 were detected at one site, and only Cs-137 was detected at another site, at a level of 1 Bq/L (detection limit: 1 Bq/L) (see the main text).

## 4.1-2 Sediment

Detection of radioactive cesium in sediment samples from public water areas (rivers, lakes, and coastal areas) is as outlined below.

#### (1) Detection status

#### 1) Rivers

Radioactive cesium detected in river sediment samples is as shown in Table 4.1.2-1 and Figure 4.1.2-1.

According to the results, including the past years, the detection rate has ranged between 50 and 100% and has been slightly decreasing over time in many prefectures.

On the other hand, as for detected values (the total of Cs-134 and Cs-137) shown in Figure 4.1.2-1, the number of locations with high concentration levels has decreased while number of locations with low concentration levels has increased. When the detected values for FY2017 were observed by the concentration category, radioactive cesium was not detectable at 26 locations (approx. 7%), less than 100 Bq/kg at 194 locations (approx. 49%) and less than 100 to 200 Bq/kg at 67 locations (approx. 17%). The locations where their detected values were less than 200 Bq/kg accounted for approximately 73% of the total surveyed locations.

#### 2) Lakes

Detection of radioactive cesium in lake sediment samples is as shown in Table 4.1.2-2 and Figure 4.1.2-2.

According to the results, including the past years, the detection rate has ranged between 83 and 100%. In FY2017, detection rates of 90% or more were observed in all prefectures.

Detected values (the total of Cs-134 and Cs-137) have increased at locations with lower concentrations, however, this trend is relatively moderate compared to those in rivers or coastal areas. The areas with higher concentrations still exist in many locations as in Hamadori District, Fukushima Prefecture where radioactive cesium was still detected at concentrations of 100,000 Bq/kg or more in FY2017. When the detected values for FY2017 are observed by the concentration category, radioactive cesium was not detectable at one location, less than 100 Bq/kg at 13 locations (approx. 8%), less than 100 to 1,000 Bq/kg at 78 locations (approx. 48%), and less than 1,000 to 3,000 Bq/kg at 35 locations (approx. 21%). The locations where their detected values were less than 3,000 Bq/kg accounted for approximately 77% of the total surveyed locations.

#### 3) Coastal areas

Detection of radioactive cesium in coastal area sediment samples is as shown in Table 4.1.2-3 and Figure 4.1.2-3.

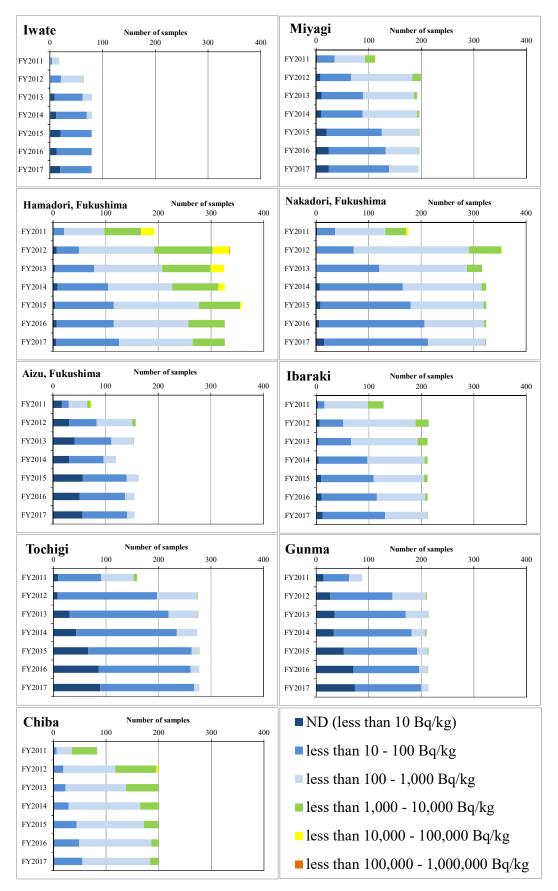

According to the results, including the past years, the detection rate ranged between 30 and 100% except for a small number of samples from Iwate Prefecture.

Coastal area locations showed lower detected values (the total of Cs-134 and Cs-137) than those in rivers or lakes. Radioactive cesium was not detected with a value of 1,000 Bq/kg or more in any prefectures in FY2017 same as in FY2016. When the detected values for FY2017 are observed by the concentration category, radioactive cesium was not detectable at nine locations (approx. 21%), less than 100 Bq/kg at 17 locations (approx. 41%), and less than 100 to 200 Bq/kg at seven locations (approx. 17%). The locations where their detected values were less

than 200 Bq/kg accounted for approximately 79% of the total surveyed locations.

Figure 4.1.2-3 Detection of radioactive cesium in coastal area sediment samples (Changes)

(2) Changes in concentration levels

Changes in overall concentration levels were evaluated based on the following method shown below by using data obtained at locations where continuous monitoring has been conducted.

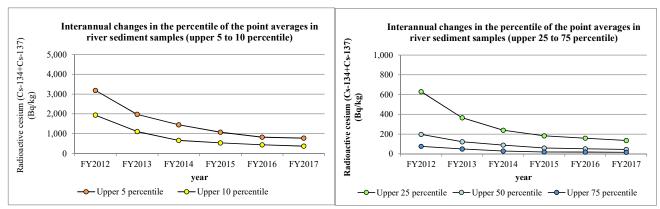

- Obtain the average value for each location where continuous monitoring has been conducted in order to
  evaluate changes in overall concentration levels of radioactive cesium each fiscal year (arithmetic average
  calculated by assuming ND to be zero; hereinafter referred to as the "average for each location").
  The analyzation of data from FY2011 was excluded, concerning a small number of samples and locations
  collected comparing to those in past years.
- Arrange all such averages for each location (separately for samples from rivers, lakes, and coastal areas) each fiscal year in descending order and set the following five categories depending on upper percentile ranges.
  - Upper 5 percentile of the entirety
  - Upper 10 percentile of the entirety
  - Upper 25 percentile of the entirety
  - Upper 50 percentile of the entirety
  - Upper 75 percentile of the entirety

(Incidentally, a correlation between the average for each location and the maximum value by fiscal year revealed a good correlation. Therefore, considering that the evaluation of the average for each location covers that of large detected values (maximum values) that emerge occasionally, the evaluation was conducted by using only the average for each location.)

#### 1) Rivers

Interannual changes in the percentile values of the point averages in river sediment samples are as shown in Figure 4.1.2-4.

Since FY2012, all percentile values have been on a decreasing trend, and in FY2017, they had declined to a level of about 20% of FY2012.

In FY2017, 95% of the total (locations below the upper 5 percentile) was less than 1,000 Bq/kg.

Figure 4.1.2-4 Interannual changes in the percentile values of the point averages in river sediment samples

## 2) Lakes

Interannual changes in the percentile values of the point averages in lake sediment samples are as shown in Figure 4.1.2-5.

Since FY2012, most of the percentile values have been on a decreasing trend, and in FY2017, they had declined to the level of about half of Y2012.

In FY2017, 90% of the total (locations below the top 10 percentile) was less than about 10,000 Bq/kg, and 75% of the total (locations below the upper 25 percentile) was less than 2,000 Bq/kg.

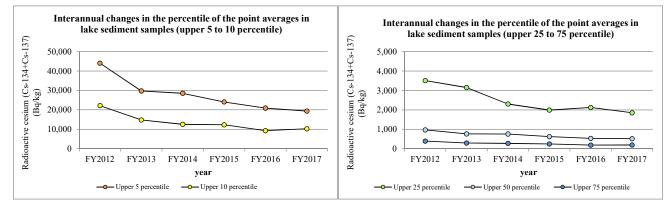

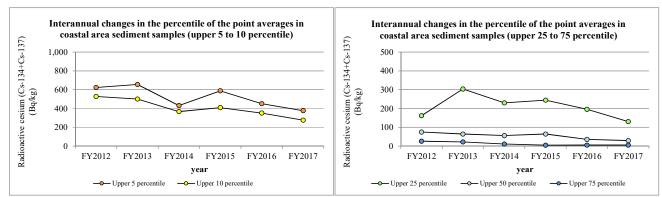

Figure 4.1.2-5 Interannual changes in the percentile values of the point averages in lake sediment samples

#### 3) Coastal areas

Interannual changes in the percentile values of the point averages in coastal area sediment samples are as shown in Figure 4.1.2-6.

Since FY2012, the percentile values have generally been decreasing except for some locations that showed some fluctuations. In FY2017, they declined to about half of those in FY2012 (In coastal areas, the concentration levels were relatively lower than those in rivers or lakes, and the number of survey locations was very small. Therefore, the percentile values showed fluctuations. Of these, the increase in 25 percentile from FY2012 to FY2013 was due to the addition of three survey locations with relatively high concentration. Another partial increase of percentile values in FY2015 was considered to be due to the heavy rains in the Kanto and Tohoku regions occurring in September 2015. This increase was a transient trend and the percentile values have continuously seen decreasing trends since FY2016 as they used to be previously.

In FY2017, 95% of the total (locations below the upper 5 percentile) was less than 400 Bq/kg.

## 4.3 Detection of radioactive materials in sediment by location

#### (1) Evaluation policy

Circumstances where radioactive materials were detected were compiled in further detail by sampling location, while separately considering the property such as rivers, lakes and coastal areas.

Circumstances for each location were statistically analyzed from the following two perspectives by using all available data for each location. Locations where the survey was completed in a single fiscal year (including Yamagata Prefecture) and where the survey has not been conducted since FY2013, were excluded from the evaluation.

#### 1) Relative detected concentration levels

- i. Obtain the average value for each location in FY2017 by using all survey results concerning concentrations of radioactive cesium (the total of Cs-134 and Cs-137) (arithmetic average calculated by assuming ND to be zero).
- ii. Arrange all such averages for each location (separately for samples from rivers, lakes, and coastal areas) in descending order and set the following five categories depending on upper percentile ranges (see Figure 4.1.2-7).
  - Category A: Upper 5 percentile of the entirety
  - Category B: Upper 5 to 10 percentile of the entirety
  - · Category C: Upper 10 to 25 percentile of the entirety
  - Category D: Upper 25 to 50 percentile of the entirety
  - Category E: Upper 50 to 100 percentile of the entirety (lower 50 percentile)

(Incidentally, a comparison between the average and the maximum value for each location in FY2017 revealed a good correlation (see lower right of Figure 4.1.2-7). Therefore, considering that the evaluation of the average for each location covers that of large detected values (maximum values) that emerge occasionally, the evaluation was conducted by using only the average for each location.)

#### 2) Changes in detected values

- i. Changes in detected values were categorized based on the following policy in order to evaluate their changes over the years.
  - (i) Based on graphs showing changes in detected values of each location over the years, those negatively sloped are set as "decreasing" and those positively sloped are set as "increasing" respectively by eye measurement.
  - (ii) When eye measurement is difficult, a regression analysis is conducted to check the trend. Specifically, when the lower and upper 95% of the slope are both negative, it is judged as "decreasing," and when the lower and upper 95% of the slope are both positive, it is judged as "increasing."
  - (iii) When increasing or decreasing tendencies are unclear (either the lower or upper limit of 95% of the slope is negative or the other is positive), a coefficient of variation of 0.5 was used as a reference. When the coefficient of variation is less than 0.5, it is judged as "unchanged," and when the coefficient

of variation is 0.5 or higher, it is judged as "fluctuations."

ii. However, data may show fluctuations, depending on minor differences in sampling locations or properties of the samples, and it is considered to be too early to make judgments on changes in detected values at this point in time. Even if a certain location is categorized as an "increasing trend" based on the abovementioned policy, whether or not the trend is increasing in a particular location requires further continuous collection of data in order to make an informed judgment.

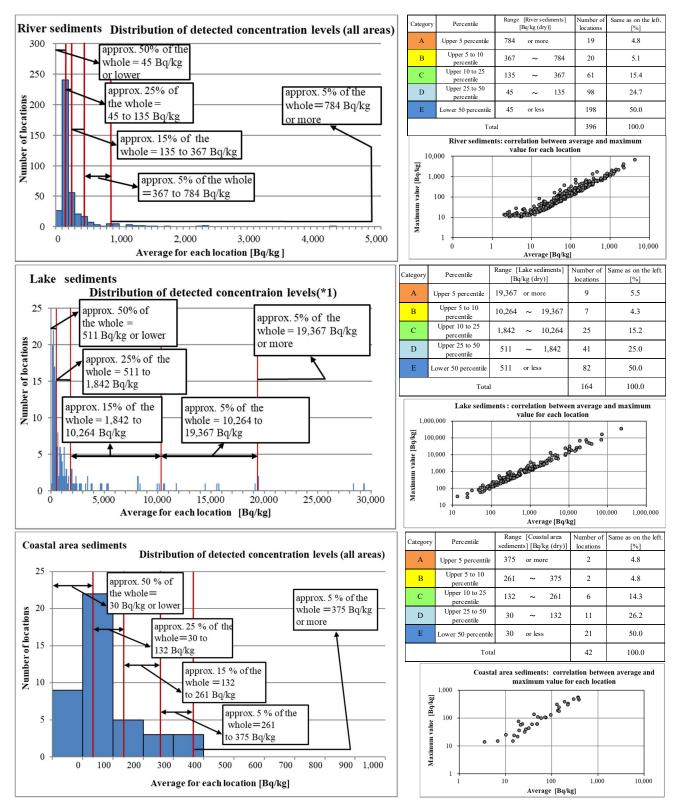

Figure 4.1.2-7 Categories based on the average for each location (left: picture showing means of categorization; upper right: results of categorization<sup>9</sup>; lower right: correlation between average and maximum value for each location)

\*1: locations where the maximum value on the horizontal axis is exceeded are not shown.

<sup>9</sup> Method of setting categorization boundary value: The boundary value of adjacent categories is the average value of the minimum value of the upper categorization and the maximum value of the lower categorization.

(2) Concentration levels in sediment samples from rivers, lakes, and coastal areas and their changes

- by prefecture
- (2)-1 Rivers
- 1) Iwate Prefecture

In Iwate Prefecture, surveys were conducted 13 to 25 times from December 2011 to February 2018 for river sediment samples collected at 22 locations (this analysis excludes the survey results from one location where the survey was conducted only in 2011).

Regarding the concentration levels of detected values, three locations were categorized as Category D and 19 locations were categorized as Category E (see Table 4.1.2-4 and Table 4.1.2-5).

Concentration levels were generally decreasing at 20 locations and were fluctuating at two locations.

# 2) Miyagi Prefecture

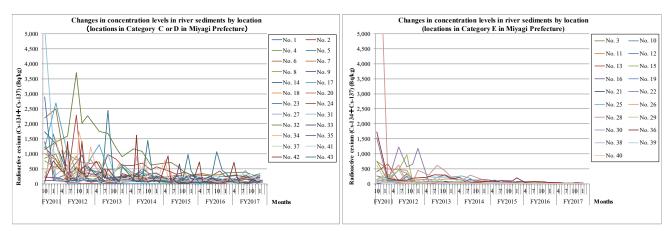

In Miyagi Prefecture, surveys were conducted 24 to 63 times from October 2011 to February 2018 for river sediment samples collected at 43 locations (this analysis excludes the survey results from 38 locations where the survey was conducted only in 2011).

Regarding the concentration levels of detected values, nine locations were categorized as Category C, 15 locations as Category D, and 19 locations as Category E (see Table 4.1.2-6 and Table 4.1.2-7).

Concentration levels were generally decreasing at 39 locations and were fluctuating at four locations.

#### 3) Fukushima Prefecture

#### (i) Hamadori

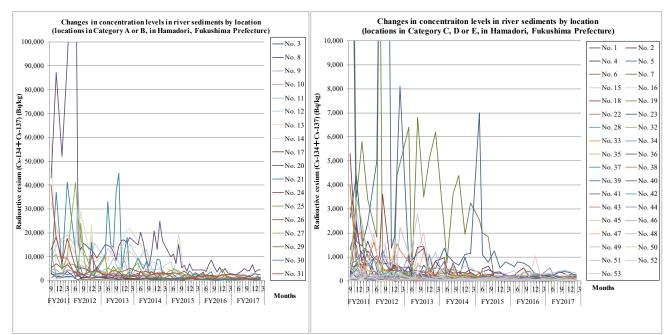

In Hamadori, Fukushima Prefecture, surveys were conducted 35 to 65 times from September 2011 to February 2018 for river sediment samples collected at 53 locations.

Regarding the concentration levels of detected values, 12 locations were categorized as Category A, six locations as Category B, 12 locations as Category C, eight locations as Category D, and 15 locations as Category E (see Table 4.1.2-8 and Table 4.1.2-9).

Concentration levels were generally decreasing at 50 locations, were unchanged at one location, were fluctuating at one location, and were increasing at one location.

Table 4.1.2-8 Categorization of detected values at respective locations	
(Hamadori, Fukushima Prefecture: river sediment)	

Category	gory Percentile Number of (percentile in all detected values) locations		Locations
А	Upper 5 percentile	12	No.3, No.11, No.12, No.13, No.14, No.20, No.21, No.24, No.25, No.26, No.27, No.30

## (ii) Nakadori

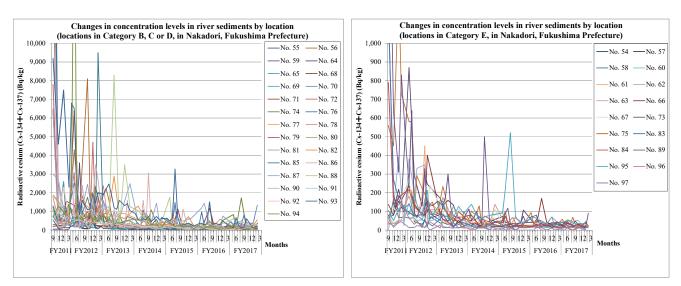

In Nakadori, Fukushima Prefecture, surveys were conducted 39 to 67 times from September 2011 to February 2018 for river sediment samples collected at 44 locations.

Regarding the concentration levels of detected values, three locations were categorized as Category B, 10 locations as Category C, 14 locations as Category D, and 17 locations as Category E (see Table 4.1.2-10 and Table 4.1.2-11).

Concentration levels were generally decreasing at 42 locations and were fluctuating at two locations.

(iii) Aizu

In Aizu, Fukushima Prefecture, surveys were conducted 30 to 59 times from September 2011 to February 2018 for river sediment samples collected at 26 locations.

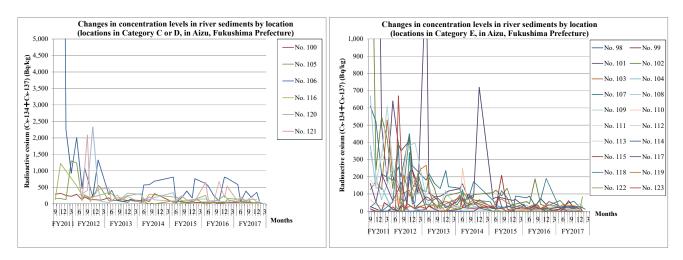

Regarding the concentration levels of detected values, one location was categorized as Category C, five locations as Category D, and 20 locations as Category E (see Table 4.1.2-12 and Table 4.1.2-13).

Concentration levels were generally decreasing at 21 locations and fluctuating at five locations.

# Table 4.1.2-13 Detection of radioactive cesium at respective locations (Aizu, Fukushima Prefecture: river sediment)

#### 4) Ibaraki Prefecture

In Ibaraki Prefecture, surveys were conducted 23 to 29 times from August 2011 to February 2018 for river sediment samples collected at 53 locations (this analysis excludes the survey results from 40 locations where the survey was conducted only in 2011).

Regarding the concentration levels of detected values, one location was categorized as Category A, three locations as Category B, 10 locations as Category C, 26 locations as Category D, and 13 locations as Category E (see Table 4.1.2-14 and Table 4.1.2-15).

Concentration levels were generally decreasing at 50 locations and fluctuating at three locations.

Category	Percentile (percentile in all detected values)	Number of locations	Locations

#### 5) Tochigi Prefecture

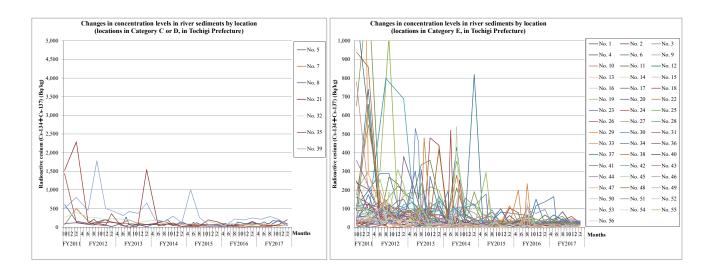

In Tochigi Prefecture, surveys were conducted 23 to 44 times from October 2011 to February 2018 at 56 locations (rivers) in public water areas (this analysis excludes the survey results from 49 locations where the survey was conducted only in 2011).

Regarding the concentration levels of detected values, one location was categorized as Category C, six locations were categorized as Category D and 49 locations were categorized as Category E (see Table 4.1.2-16 and Table 4.1.2-17).

Concentration levels were generally decreasing at 49 locations and fluctuating at seven locations.

Category	Percentile (percentile in all detected values)	Number of locations	Locations

#### 6) Gunma Prefecture

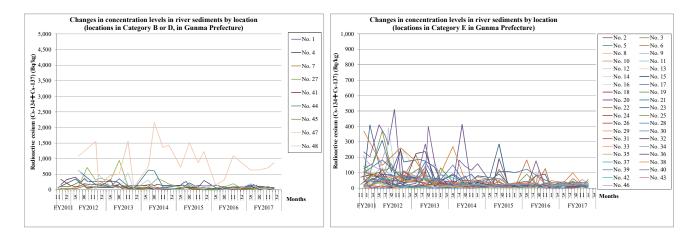

In Gunma Prefecture, surveys were conducted 14 to 44 times from November 2011 to January 2018 at 48 locations (rivers) in public water areas (this analysis excludes the survey results from eight locations where the survey was conducted only in 2011).

Regarding the concentration levels of detected values, one location was categorized as Category B, eight locations as Category D, and 39 locations as Category E (see Table 4.1.2-18 and Table 4.1.2-19).

Concentration levels were generally decreasing at 39 locations and fluctuating at nine locations.

#### 7) Chiba and Saitama Prefectures and Tokyo Metropolis

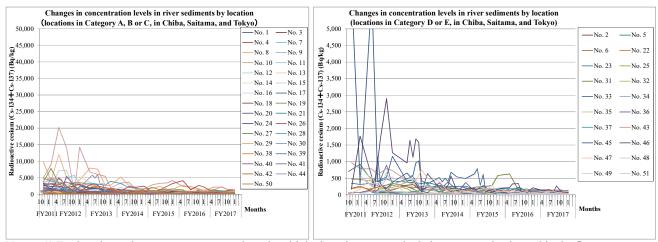

In Chiba and Saitama Prefectures and Tokyo Metropolis, surveys were conducted 24 to 43 times from October 2011 to January 2018 at 51 locations (rivers) in public water areas (47 locations in Chiba Prefecture, two locations in Saitama Prefecture, and two locations in Tokyo Metropolis).

Regarding the concentration levels of detected values, six locations were categorized as Category A, seven locations as Category B, 18 locations as Category C, 13 locations as Category D, and seven locations as Category E (see Table 4.1.2-20 and Table 4.1.2-21).

Concentration levels were generally decreasing at 46 locations and fluctuating at five locations.

(2)-2 Lakes

## 1) Miyagi Prefecture

In Miyagi Prefecture, surveys were conducted 13 to 25 times from October 2011 to December 2017 for lake sediment samples collected at 21 locations.

Regarding the concentration levels of detected values, one location was categorized as Category C, three locations were categorized as Category D and 17 locations were categorized as Category E (see Table 4.1.2-22 and Table 4.1.2-23).

Concentration levels were generally decreasing at 13 locations, unchanged at two locations, and fluctuating at six locations.

#### 2) Fukushima Prefecture

### (i) Hamadori

In Hamadori, Fukushima Prefecture, surveys were conducted 25 to 64 times from September 2011 to February 2018 for lake sediment samples collected at 41 locations.

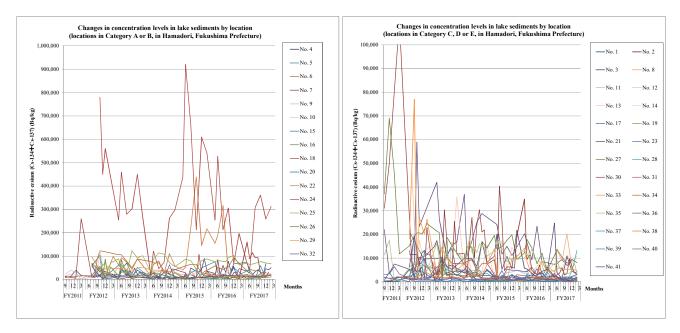

Regarding the concentration levels of detected values, nine locations were categorized as Category A, seven locations as Category B, 11 locations as Category C, 10 locations as Category D, and four locations as Category E (see Table 4.1.2-24 and Table 4.1.2-25).

Concentration levels were generally decreasing at 22 locations, were unchanged at three locations, were fluctuating at 15 locations, and were generally increasing at one location.

 Table 4.1.2-21 Categorization of detected values at respective locations

#### (ii) Nakadori

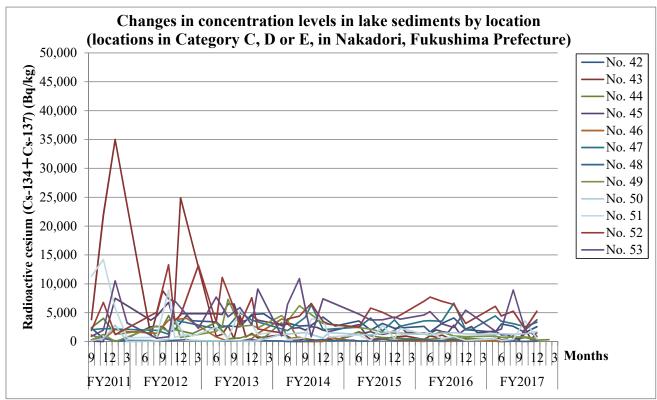

In Nakadori, Fukushima Prefecture, surveys were conducted 32 to 54 times from September 2011 to February 2018 for lake sediment samples collected at 12 locations.

Regarding the concentration levels of detected values, four locations were categorized as Category C, five locations as Category D, and three locations as Category E (see Table 4.1.2-26 and Table 4.1.2-27).

Concentration levels were generally decreasing at five locations, unchanged at two locations, fluctuating at four locations, and were generally increasing at one location.

(iii) Aizu

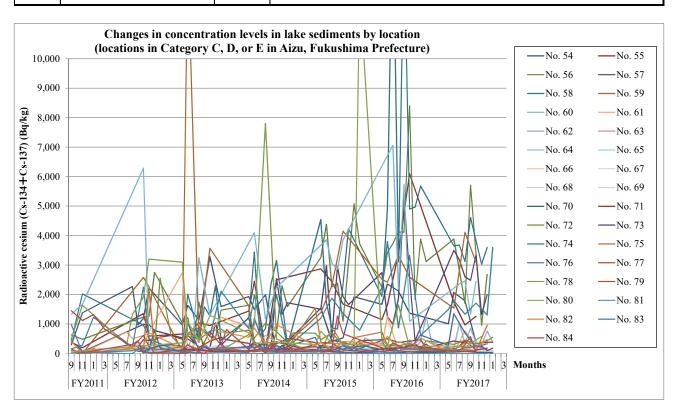

In Aizu, Fukushima Prefecture, surveys were conducted 22 to 58 times from September 2011 to January 2018 for lake sediment samples collected at 31 locations.

Regarding the concentration levels of detected values, six locations were categorized as Category C, four locations were categorized as Category D and 21 locations were categorized as Category E (see Table 4.1.2-28 and Table 4.1.2-29).

Concentration levels were generally decreasing at nine locations, unchanged at three locations, fluctuating at 13 locations, and increasing at six locations.

## Table 4.1.2-29 Detection of radioactive cesium at respective locations

## (Aizu, Fukushima Prefecture: lake sediment)

#### 3) Ibaraki Prefecture

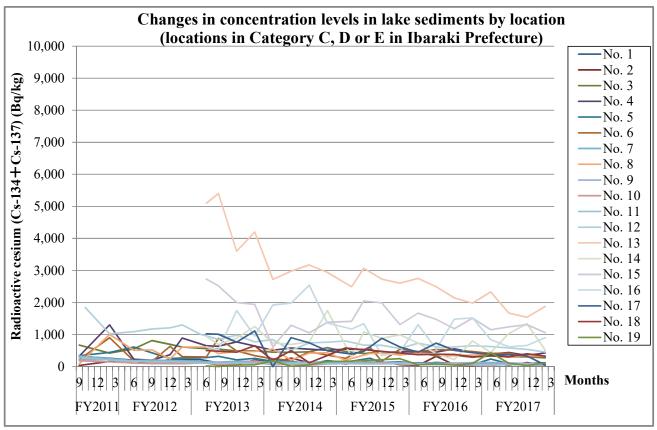

In Ibaraki Prefecture, surveys were conducted 17 to 26 times from September 2011 to February 2018 for lake sediment samples collected at 19 locations.

Regarding the concentration levels of detected values, one location was categorized as Category C, four locations as Category D, and 14 locations as Category E (see Table 4.1.2-30 and Table 4.1.2-31).

Concentration levels were generally decreasing at 11 locations, unchanged at five locations, and fluctuating at three locations.

### 4) Tochigi Prefecture

In Tochigi Prefecture, surveys were conducted 22 to 26 times from October 2011 to December 2017 for lake sediment samples collected at eight locations.

Regarding the concentration levels of detected values, two locations were categorized as Category D, and six locations as Category E (see Table 4.1.2-32 and Table 4.1.2-33).

Concentration levels were generally decreasing at three locations, fluctuating at three locations, and increasing at two locations.

#### 5) Gunma Prefecture

In Gunma Prefecture, surveys were conducted 20 to 26 times from November 2011 to December 2017 for lake sediment samples collected at 24 locations.

Regarding the concentration levels of detected values, one location was categorized as Category C, 12 locations were categorized as Category D and 11 locations were categorized as Category E (see Table 4.1.2-34 and Table 4.1.2-35).

Concentration levels were generally decreasing at 11 locations, unchanged at six locations, fluctuating at five locations, and increasing at two locations.

#### 6) Chiba Prefecture

In Chiba Prefecture, surveys were conducted 26 times from November 2011 to February 2018 for lake sediment samples collected at eight locations.

Regarding the concentration levels of detected values, one location was categorized as Category C, one location into Category D, and six locations as Category E (see Table 4.1.2-36 and Table 4.1.2-37).

Concentration levels were generally decreasing at all eight locations.

## (2)-3 Coastal areas

### 1) Iwate Prefecture

In Iwate Prefecture, surveys were conducted 13 times from January 2012 to November 2017 for coastal area sediment samples collected at two locations (this analysis excludes the survey results from one location where the survey was conducted only in FY2011).

Regarding the concentration levels of detected values, both locations were categorized as Category E (see Table 4.1.2-38 and Table 4.1.2-39).

Concentration levels were unchanged at one location and fluctuating at the other location.

#### 2) Miyagi Prefecture

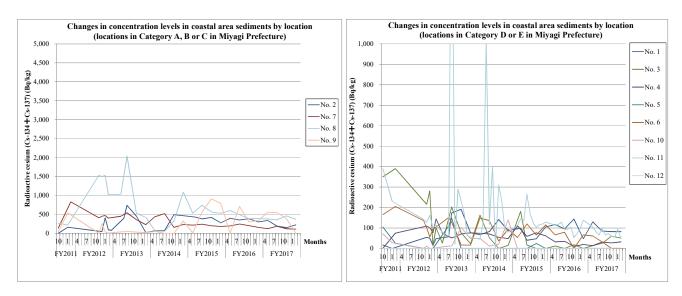

In Miyagi Prefecture, surveys were conducted 13 to 57 times from October 2011 to February 2018 for coastal area sediment samples collected at 12 locations (this analysis excludes the survey results from 28 locations where the survey was conducted only in FY2011).

Regarding the concentration levels of detected values, one location was categorized as Category A, one location into Category B, two locations as Category C, three locations as Category D, and five locations as Category E (see Table 4.1.2-40 and Table 4.1.2-41).

Concentration levels were generally decreasing at six locations, unchanged at one location, fluctuating at four locations, and increasing at one location.

#### 5) Chiba Prefecture and Tokyo Metropolis

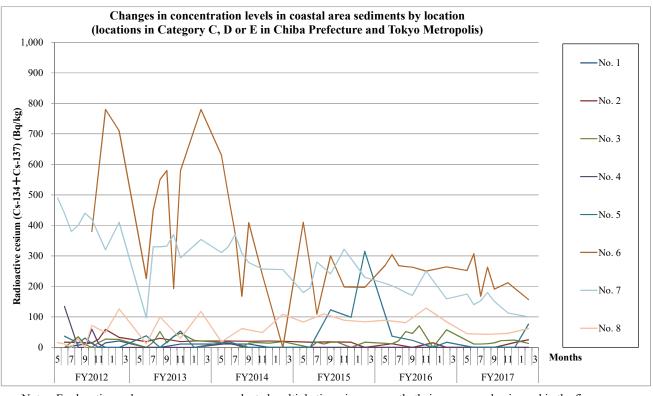

In Chiba Prefecture and Tokyo Metropolis, surveys were conducted 25 to 43 times from May 2012 to February 2018 for coastal area sediment samples collected at eight locations in total.

Regarding the concentration levels of detected values, two locations were categorized as Category C, one location was categorized as Category D and five locations were categorized as Category E (see Table 4.1.2-46 and Table 4.1.2-47).

Concentration levels were generally decreasing at five locations, unchanged at one location and fluctuating at two locations.

# Table 4.1.2-46 Categorization of detected values at respective locations(Chiba Prefecture and Tokyo Metropolis: coastal area sediment)

Category	Percentile (percentile in all detected values)	Number of locations	Locations

## Table 4.1.2-47 Detection of radioactive cesium at respective locations

## (Chiba Prefecture and Tokyo Metropolis: coastal area sediment)

### 2)-4 Conclusion

The concentration levels of detected values for sediment samples from public water areas (rivers, lakes, and coastal areas) from FY2011 to FY2017 and their changes shown so far are summarized as follows (see Figure 4.1.2-30 and Table 4.1.2-48).

### 1) Concentration levels of detected values

Rivers

Out of all surveyed locations (396 locations), the number categorized as Categories A and B, which fall under the upper 10%, was the largest in Hamadori in Fukushima Prefecture (18 locations). Other such locations were also found in Nakadori in Fukushima Prefecture, Ibaraki Prefecture, Gunma Prefecture and Chiba Prefecture.

### Lakes

Out of all surveyed locations (164 locations), locations categorized as Category A or B were found in Hamadori in Fukushima Prefecture.

### Coastal areas

Out of all surveyed locations (42 locations), locations categorized as Category A or B were found in Miyagi and Fukushima Prefectures.

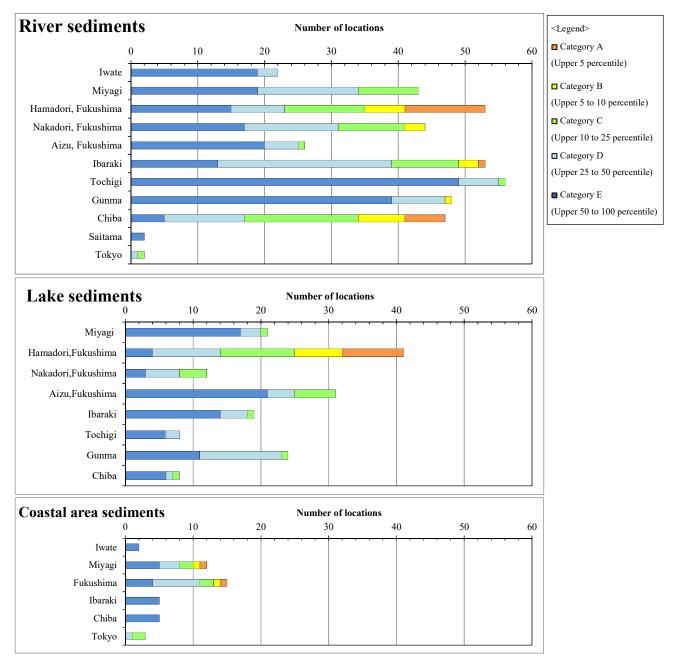

Figure 4.1.2-30 Categorization by concentration levels of detected values for sediment samples

(upper: rivers; middle: lakes; lower: coastal areas)

(\* Figure 4.1.2-30 shows the aforementioned Table 3.1-1 graphically.)

## 2) Changes in detected values

Rivers

A decreasing trend was observed at most locations.

Lakes

Mostly a decreasing or an unchanged trend was observed but some locations showed fluctuations.

Coastal areas

Mostly a decreasing trend was observed but some locations showed fluctuations.

#### 3) Summary by prefecture

Concentration levels of detected values and their changes are summarized by prefecture as follows (see Figures 4.1.2-31 to 4.1.2-33).

#### (i) Iwate Prefecture

- For rivers, all the 22 surveyed locations were categorized as either Category D or E. A decreasing trend was observed at most locations.
- For coastal areas, the two surveyed locations were categorized as Category E. An unchanged trend was observed at most locations except for some locations that showed fluctuations.

#### (ii) Miyagi Prefecture

- For rivers, of the 43 surveyed locations, some locations in the lower reaches were categorized as Category C, but over 80% of the surveyed locations were categorized as Category D or E. A decreasing trend was observed at most locations.
- For lakes, of the 21 surveyed locations, most locations were categorized as Category D or E, while one location was categorized as Category C. Concentration levels were generally decreasing except for some locations that showed fluctuations.
- For coastal areas, approximately 70% of the 12 surveyed locations were categorized as Category D or E, rest of them were categorized as Category A, B or C. There was a location categorized as Category A in the Sendai Port. Although concentration levels were fluctuating at some locations, most other locations showed decreasing or unchanged trends.
- (iii) Hamadori, Fukushima Prefecture
  - For rivers, approximately 60% of the 53 surveyed locations were categorized as Category A, B or C.
  - Many locations categorized as Category A or B were found near to or between the northern and northwest of Fukushima Daiichi NPS, while locations categorized as Category C were seen in the southern parts of the district. A decreasing trend was observed at most locations.
  - For lakes, approximately 70% of the 41 surveyed locations were categorized as Category A, B or C.
  - Many locations categorized as Category A or B were found northwest of Fukushima Daiichi NPS. Mostly a decreasing or an unchanged trend was observed except for some locations that showed fluctuations.
  - For coastal areas, approximately 70% of the 15 surveyed locations were categorized as Category D or E, and the rest were categorized as Category A, B, or C. One location categorized as Category A was seen in Onahama port. A decreasing trend was observed at most locations.

(iv) Nakadori, Fukushima Prefecture

- For rivers, more than 70% of the 44 surveyed locations were categorized as Category D or E, and the rest were categorized as Category B or C. Many locations categorized as Category B or C were found between the center and the northern part of the Abukuma River system. A decreasing trend was observed at most locations.
- For lakes, eight of the 12 surveyed locations were categorized as Category D or E, and the remaining four locations were categorized as Category C. The locations categorized as Category C were seen in the upper and lower reaches of the Abukuma River basin. A decreasing or an unchanged trend was observed at most

locations except for some locations that showed fluctuations.

- (v) Aizu, Fukushima Prefecture
  - For rivers, one of the 26 surveyed locations was categorized as Category C, and all the remaining locations were categorized as Category D or E. A decreasing trend was observed at most locations.
  - For lakes, six of the 31 surveyed locations were categorized as Category C, and approximately 80% of the locations were categorized as Category D or E. Although concentration levels were fluctuating at some locations, decreasing or unchanged trends were mostly observed at rest of the locations.
- (vi) Ibaraki Prefecture
  - For rivers, approximately 70% of the 53 surveyed locations were categorized as Category D or E, and the rest were categorized as Category A, B, or C. The locations categorized as Category A or B were found in rivers flowing into Lake Kasumigaura. A decreasing trend was observed at most locations.
  - For lakes, out of the 19 surveyed locations, one in the northern part of the prefecture was categorized as Category C, and the remaining locations were categorized as Category D or E. A decreasing or an unchanged trend was observed at most locations.
  - For coastal areas, all the five surveyed locations were categorized as Category E. A decreasing trend was observed at most locations.
- (vii) Tochigi Prefecture
  - For rivers, one of the 56 surveyed locations was categorized as Category C, and the remaining locations were categorized as Category D or E. A decreasing trend was observed at most locations.
  - For lakes, all eight locations were categorized as Category D or E. Concentration levels were fluctuating at many of the locations, and rest of the locations showed a variety of trends.

#### (viii) Gunma Prefecture

- For rivers, out of the 48 surveyed locations, some locations in the lower reaches of the Watarase River basin were categorized as Category B, and all the remaining locations were categorized as Category D or E. Mostly a decreasing trend was observed.
- For lakes, one of the 24 surveyed locations were categorized as Category C, and the remaining locations were all categorized as Category D or E. Mostly a decreasing or an unchanged trend was observed.
- (ix) Chiba and Saitama Prefectures and Tokyo Metropolis
  - For rivers, over 60% of the 51 surveyed locations were categorized as Category A, B, or C. The locations categorized as Category A or B were found in rivers flowing into Lake Teganuma or Lake Inbanuma, the Edogawa River system and a part of the Tonegawa River system. A decreasing trend was observed at most locations.
  - For lakes, one of the eight surveyed locations, in Lake Teganuma, was categorized as Category C, and all the remaining locations were categorized as Category D or E. A decreasing trend was observed at all locations.
  - For coastal areas, one of the eight surveyed locations, the mouth of the Kyuedogawa River, was categorized as Category C, and all remaining locations were categorized as Category D or E. Mostly a decreasing trend was observed except for some locations showing fluctuations.

### 5 Results (Radionuclides other than radioactive cesium)

#### 5.1 Radioactive strontium (Sr-90 and Sr-89)

#### (1) Public water areas

In principle, radioactive strontium was measured at locations where the radioactive cesium concentration in the sediment was high. (detection limit: approx.1 Bq/kg for Sr-90 and approx. 2 Bq/kg for Sr-89, both for sediment samples).

From FY2016 to FY2017, Sr-90 was surveyed (detection limit: approx. 1 Bq/L for Sr-90 for water samples) for the water samples collected on the same day from the same public water area (lakes) sediment samples where Sr-90 concentration levels were relatively high (1.0 Bq/kg or more in FY2016 and 10 Bq/kg or more in FY2017). On the other hand, a survey was conducted for Sr-89 on 22 samples (13 river sediment samples and nine lake sediment samples) in FY2011, Sr-89 was not detectable in any of them, and the survey has not been conducted since FY2012.

### 1) Sediment

#### (i) River sediment

Sr-90 was detected at eight out of 24 river sediment samples surveyed in FY2017 (detection rate: 33.3%). Detected values were less than 1 Bq/kg (see Table 4.2-1).

Sr-90 has been continuously detected since FY2011 at some locations in Ota River and Ukedo River in Fukushima Prefecture, but the detected values have gradually decreased to fall below 2 Bq/kg from FY2014 on (see Figure 4.2-1).

#### (ii) Lake sediment

In FY2017, 70 lake sediment samples were surveyed for Sr-90; Sr-90 was detected at 66 samples (detection rate: 94.3%) (see Table 4.2-1).

Sr-90 has been continuously detected until FY2017 in each prefecture surveyed.

When reviewed location by location, detected values have basically been at relatively low levels, and the range of measured values in FY2017 was from not detectable to 22 Bq/kg (see Figure 4.2-1).

#### (iii) Coastal area sediment

In FY2017, 32 coastal area sediment samples were surveyed; Sr-90 was not detectable in any of them (see Table 4.2-1).

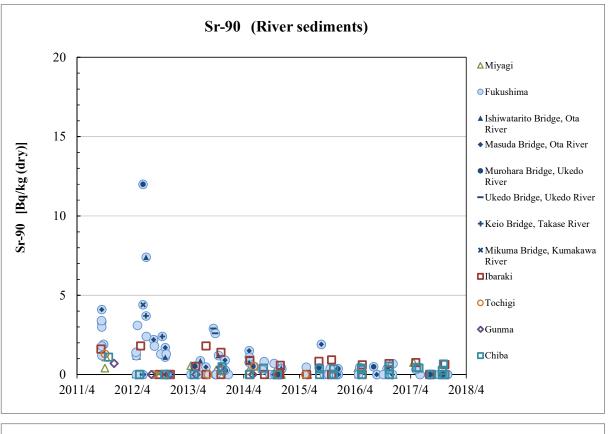

#### 2) Water

Surveys for Sr-90 on three samples collected from water area (lakes) were conducted in FY2017. Sr-90 was not detectable at any surveyed locations even in measurements at the lower limit value (0.038 to 0.047 Bq/L) which was even lower than 1 Bq/L.

				FY2017					FY	2011 - FY2	2017	Range of measured values [Bq/kg]         ND       -       1.2         ND       -       12         ND       -       1.8         ND       -       1.3         ND       -       1.1         ND       -       1.1         ND       -       1.1         ND       -       12         ND       -       1.2         ND       -       1.3         ND       -       1.1         ND       -       12         ND       -       12         ND       -       12         ND       -       12         ND       -       150         ND       -       7.0

# Table 4.2-1 Detection of Sr-90 in sediment samples from public water areas (rivers, lakes, and coastal areas)

o Sr-90

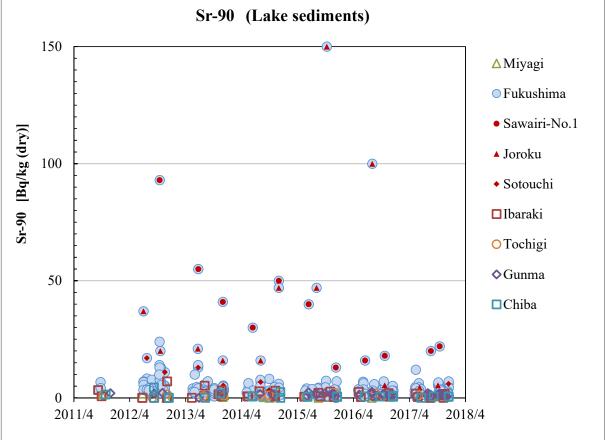

Figure 4.2-1 Detection of Sr-90 in sediment samples from public water areas (upper: rivers; lower: lakes)

### (2) Groundwater

Surveys for Sr-89 and Sr-90 were conducted on approximately 340 groundwater samples collected in Fukushima Prefecture between January 2012 and November 2017.

An outline of these survey results is as shown in Table 4.2-2. Detected values of Sr-89 and Sr-90 were all below the detection limit (1 Bq/L).

			Sr-90		Sr-89					
Year (FY)	Number of samples	Detection times	Detection rate (%)	Range of measured values (Bq/L) (*1)	Number of samples	Detection times	Detection rate (%)	Range of measured values (Bq/L) (*1)		
FY2011	8	0	0.0	ND	8	0	0.0	ND		
FY2012	60	0	0.0	ND	60	0	0.0	ND		
FY2013	77	0	0.0	ND	77	0	0.0	ND		
FY2014	48	0	0.0	ND	48	0	0.0	ND		
FY2015	48	0	0.0	ND	48	0	0.0	ND		
FY2016	48	0	0.0	ND	48	0	0.0	ND		
FY2017	48	0	0.0	ND	48	0	0.0	ND		
Total	337	0	0.0	ND	337	0	0.0	ND		

\*1: Results were compiled by setting the detection limit at 1 Bq/L.

Additionally, the detection limit of Sr-90 was 0.0002 Bq/L in FY2011, and 1 Bq/L thereafter, and similarly, the detection limit of Sr-89 was 0.001 Bq/L in FY2011, and 1 Bq/L thereafter.

In the FY2011 survey (calendar year 2012), Sr-90 was detected in all eight samples, with detected values ranging from 0.0004 to 0.0029 Bq/L. Similarly, while the detection limit for Sr-89 was 0.001 Bq/L in FY2011 (calendar year 2012), Sr-89 in all eight samples was below the detection limit.

### 5.2 Other γ-ray emitting radionuclides

Apart from the aforementioned radionuclides (Cs-134, Cs-137, Sr-89 and Sr-90), measurement results for water samples and sediment samples using a germanium semiconductor detector were analyzed from FY2011 to FY2017 to obtain activity concentrations of accident-derived radionuclides (Ag-110m, Te-129m, Nb-95, Sb-125 and Ce-144, etc.<sup>10</sup>) and major naturally occurring radionuclides such as K-40. The summary of the results is as shown in Table 4.2-3 and Table 4.2-4.

Among the detected radionuclides, no artificial radionuclides were detected in water samples for FY2011 and FY2012, while two types of radionuclides, Ag-110m and Sb-125, were detected in sediment samples with detection rates of 1% or less. Since FY2013, neither radionuclide has been detected.

Although six naturally occurring radionuclides (K-40, Pb-212, Pb-214, Tl-208, Ac-228 and Bi-214) were detected, K-40 is a naturally occurring radionuclide entrained during the Earth's formation, while the other species are all either uranium series or thorium series radionuclides, which are widely distributed in nature including the Earth's crust.

Year	Number	Major de	tected artificial radionuclide	Major detected naturally occurring radionuclide			
(FY)	of samples	Nuclide	Detection rate and detected values	Nuclide	Detection rate		
FY2011	1,755	-	-	K-40	10%		
FY2012	3,518	-	-	K-40	6%		
FY2013	3,860	-	-	K-40	13%		
FY2014	3,856	-	-	K-40	10%		
FY2015	3,916	-	-	K-40 Pb-212 Pb-214	7% 7% 9%		
FY2016	3,890	-	-	K-40 Pb-212 Pb-214	8% 17% 10%		
FY2017	3,836	-	-	K-40 Pb-214	7% 8%		

Table 4.2-3 Detection of other radionuclides (Water)

<sup>&</sup>lt;sup>10</sup> Among the accident-derived radionuclides, I-131 was investigated in water samples from public water areas (3,111 river water samples, 1,416 lake water samples, and 715 coastal area water samples) and sediment samples (3,073 river sediment sample, 877 lake sediment samples, and 393 coastal area sediment samples) from FY 2011 to FY 2012, and in groundwater samples (3,793 samples) from FY 2011 to FY 2014. In none of these samples was I-131 detected (detection limit values: 1 Bq/L for water and 10 Bq/kg for sediment).

V	Number	Major det	ected artificial radionuclide	Major detected naturally occurring radionuclide			
Year (FY)	of samples	Nuclide	Detection rate and detected values	Nuclide	Detection rate
